A molecular vibration is a periodic motion of the atoms of a molecule relative to each other, such that the center of mass of the molecule remains unchanged. The typical vibrational frequencies range from less than 10 13 Hz to approximately 10 14 Hz, corresponding to wavenumbers of approximately 300 to 3000 cm <sup>-1</sup> and wavelengths of approximately 30 to 3 μm. ...

The very fast transitions in BaF 2 and CsF are due to an intermediate transition between the valence and core bands. E vv < E g fast fluorescence E vv > E g emission of Auger electron (energy released in the transition from the valence to the core band does not go into photon emission, but into emission of an electron to the conduction band)

The observed substructure of the CdSe absorption spectrum and the oscillator strength of allowed transitions was modeled theoretically by Ekimov et al. [30]. They based their theory on the spherical confinement, the valence band degeneracy, the nonparabolicity of the conduction band, and the coulomb interaction between the electrons and the holes.

The energy of an electron is mainly determined by the values of the principal and orbital quantum numbers. The principal quantum number is simply expressed by giving that number, but the orbital quantum number is denoted by a letter. These letters, which are derived from the early days of spectroscopy, are s, p, d and f, which signify that the orbital quantum numbers l are 0, 1, 2 and 3 ...
